ABSTRACT: An improved chemical one-step method (ICOSM) was used to prepare highly conductive and magnetic polypyrrole/ γ -Fe₂O₃ (PPy/ γ -Fe₂O₃) nanospheres \sim 80 nm in diameter. In the reaction process involved, FeCl₃ acts as an oxidant for the polymerization of pyrrole and as a source of Fe^{III} for the formation of γ -Fe₂O₃, which also requires the initial presence of Fe^{II}, provided by the addition of FeCl₂. The method differs from the previous chemical one-step method (COSM) through the addition of *p*-toluenesulfonic acid (*p*-TSA) as the dopant after addition of the FeCl₃ solution was finished. The conductive and magnetic properties of PPy/ γ -Fe₂O₃ nanospheres increased and reached maximum values simultaneously with increasing amounts of FeCl₂, contrary to the result observed in the previous COSM. The resulting electromagnetic PPy/ γ -Fe₂O₃ nanospheres show maximum conductivity of 64.4 S/cm and saturation magnetization of 4.85 A m²/kg. The *p*-TSA dopant plays a critical role in the formation of PPy/ γ -Fe₂O₃ nanospheres.

1. INTRODUCTION

Electromagnetically functionalized micro/nanostructures of conducting polymers are of special interest due to their potential applications in areas such as electromagnetic interference shielding,¹ microwave absorption,² nonlinear optics,³ molecular electronics,⁴ and biomedicine.⁵ Previously, polyaniline (PANI) nanotubes containing Fe₃O₄ nanoparticles (\sim 10 nm in diameter) have been prepared by an in-situ chemical oxidation polymerization (two-step method) in the presence of Fe₃O₄ nanoparticles.⁶ The magnetic nanoparticles were prepared initially and were then incorporated in the oxidation polymerization of aniline to form the PANI/Fe₃O₄ nanotubes via a self-assembly process. We have also reported that coaxial PANI/ γ -Fe₂O₃ nanofibers may be prepared by using γ -Fe₂O₃ nanoneedles as templates.⁷ The above in-situ methods suffer from the limitation that the added magnetic particles rapidly aggregate, and so it is difficult to disperse them uniformly in the PANI matrix. More recently, we developed a very simple chemical one-step method (COSM) to prepare PANI/ γ -Fe₂O₃ nanofibers.⁸ The advantage of the COSM is that FeCl₃ acts as the oxidant for polymerization of aniline and as a source of Fe^{III} for the preparation of γ -Fe₂O₃ magnets, which results in a simultaneous preparation of the conducting polymer and the magnetic material, to form the electromagnetically functionalized composite nanofibers via a self-assembly process. By using this COSM, the magnetic γ -Fe₂O₃ nanoparticles can be integrated uniformly in the conducting polymer matrix. Thus, it is a simple and economical route to

obtain electromagnetically functionalized composites in large quantity. However, all these electromagnetically functionalized PANI nanostructures show relatively low room-temperature conductivity (10^{-2} – 10^0 S/cm). In particular, good magnetic properties were usually accompanied by low electrical conductivity. Compared with PANI, polypyrrole (PPy) has a high conductivity, which encouraged researchers to synthesize electromagnetically functionalized PPy nanostructures using the above COSM. Thus, Xiao et al. have reported PPy/FeOOH nanospheres with a high conductivity of 16.1 S/cm by using the COSM.⁹ However, the maximum saturation magnetization only is 0.11 A m²/kg. Therefore, the preparation of a nanostructured conducting polymer composite with high electrical conductivity without compromising the magnetic properties is still a challenge.

In the present study, an improved chemical one-step method (ICOSM) was proposed to prepare uniform electromagnetic PPy/ γ -Fe₂O₃ nanospheres with high conductivity and good magnetization. In our previously reported COSM,⁸ no dopants were added into the polymerization solution. In order to get highly conductive composite nanostructures, *p*-TSA was added as dopant after the addition of FeCl₃ solution was finished. Through this ICOSM, the conductivity and magnetization can be

Revised: May 17, 2011

Published: May 26, 2011

increased simultaneously by controlling the amounts of FeCl_2 , which is added as the source of Fe^{II} that is required for the formation of $\gamma\text{-Fe}_2\text{O}_3$.¹⁰ Of the resulting PPy/ $\gamma\text{-Fe}_2\text{O}_3$ nanosphere products, the one that showed the maximum room temperature conductivity (64.4 S/cm) also had the highest saturation magnetization ($M_s = 4.85 \text{ A m}^2/\text{kg}$).

2. EXPERIMENTAL PART

2.1. Chemicals. Pyrrole monomer (Py) was distilled under reduced pressure. Other reagents, such as ferric chloride ($\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$), ferrous chloride ($\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$), *p*-toluenesulfonic acid (*p*-TSA), and ammonium hydroxide (NH_4OH), were used as received without further purification.

2.2. Synthetic Method. A typical ICOSM procedure for the synthesis of electromagnetically functionalized PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres is as follows: Pyrrole monomer (0.133 mL, 2 mmol) was dissolved in aqueous ammonia solution (10 mL of 1.0 M) with ultrasonic stirring for 1 min to form white emulsion. Then a solution of $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ (30 mg, 0.014 mmol) in water (5 mL) was added to the above emulsion, to yield a pale blue solution. To this was added a solution of $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ (3.24 g, 12 mmol) in water (10 mL), dropwise at a rate of 1 mL/min, whereupon the solution immediately turned brown. During the addition of the FeCl_3 solution, the reaction solution was kept at $0\text{--}4^\circ\text{C}$ with stirring at the rate of 600 rpm. A quantity of *p*-TSA (0.34 g, 2 mmol) was added after addition of the FeCl_3 solution was finished. The reaction solution was stirred for 12 h. The resulting product was collected by centrifuging at 4000 rpm for 5 min. The powder was washed with distilled water, ethanol, and ether three times, respectively. Finally, the powder was dried under vacuum at room temperature for 24 h. The molar ratio of *p*-TSA to Py ($[\text{TSA}]/[\text{Py}]$) and the amounts of $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ added (expressed as $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$, the ratio of added $[\text{Fe}^{\text{II}}]$ relative to initial $[\text{Fe}^{\text{III}}]$) were varied to investigate the effect of the preparation conditions on the morphology and on the electrical and magnetic properties of the PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composites.

2.3. Measurements. The morphology of the products was characterized by scanning electron microscopy (SEM, Hitachi-530 or FESEM, JSM-6700F). The room temperature conductivity was measured by a Keithley 196 SYSTEM DM digital multimeter and an ADVANTEST R6142 programmable dc voltage/current source using a standard four-probe method. The chemical structure was characterized by FTIR, XPS, and X-ray diffraction. The FTIR spectra of the composites in KBr pellets were recorded using an IFS-113 V instrument. XPS data were obtained with an ESCALab220i-XL electron spectrometer using Al K α radiation under a base pressure of about 3×10^{-9} Torr. The binding energies were referenced to the C 1s line at 284.8 eV from adventitious carbon. X-ray diffraction was measured by a Micscience Model M18XHF diffractometer (MAC SCIENCE, Japan). Magnetization with an applied magnetic field (i.e., a hysteresis loop) at room temperature were carried out by using a vibrating sample magnetometer (VSM, Lakeshore 7307) with a maximum magnetic field of 795.77 kA/m.

3. RESULTS AND DISCUSSION

3.1. Electrical and Magnetic Properties of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ Nanospheres. In our previous COSM, the conductivity of PANI/ $\gamma\text{-Fe}_2\text{O}_3$ nanofibers is only as high as 1.2 S/cm. Although Xiao et al.⁹ reported that PPy/ FeOOH nanospheres prepared by COSM can reach 16.1 S/cm, the saturation magnetization of $0.11 \text{ A m}^2/\text{kg}$ is too low. In the preparation process of both PANI/ $\gamma\text{-Fe}_2\text{O}_3$ nanofibers and PPy/ FeOOH nanospheres, increasing the FeCl_2 amount results in more magnetic particles

Figure 1. Effect of the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratios on the conductivity and saturation magnetization of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres.

formed, which is favorable for good magnetic properties. However, increasing the FeCl_2 amount leads to decreased conductivity of the PANI/ $\gamma\text{-Fe}_2\text{O}_3$ nanospheres. That is to say, it is hard to obtain the best electrical and magnetic properties at the same time using previous COSM. For our ICOSM, the enhancement caused by the FeCl_2 is favorable for both the electrical and magnetic properties when the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio is lower than 0.046, which can be seen clearly from Figure 1. The conductivity of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres increases from 42.9 to 64.4 S/cm with an increase in the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio from 0.014 to 0.046. At the same time, the saturation magnetization of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres also increases from 0.96 to 4.85 $\text{A m}^2/\text{kg}$ when the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio increases from 0.014 to 0.046. Moreover, the conductivity and the saturation magnetization of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ nanospheres simultaneously reached maxima of 64.4 S/cm and 4.85 $\text{A m}^2/\text{kg}$, respectively, when the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio is 0.046. This positive increase of conductivity and magnetization with the increase of FeCl_2 amounts in this ICOSM is contrary to that observed in the previous COSM, in which the conductivity of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres decreased with an increase in the amount of FeCl_2 . All resulting PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanosphere products in this ICOSM show high conductivity of 42.9–64.4 S/cm (as shown in Figure 1), which is greater by more than 3 orders magnitude compared with that of PANI/ Fe_3O_4 nanotubes ($\sim 10^{-2}$ S/cm)⁶ and by ~ 50 times compared with those of the PANI composite nanofibers (1.2 S/cm) and PPy/ Fe_3O_4 nanoparticles (1.0 S/cm) by using the previous COSM.^{8,11} Also, the conductivity of 42.9–64.4 S/cm for PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres obtained by using ICOSM is greater than that of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite (16.3 S/cm) prepared without *p*-TSA according to our previous COSM.⁸ All these significant results can be attributed to the addition of *p*-TSA after addition of the FeCl_3 solution was finished. The reason that the conductivity of PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres increased with increasing the amount of FeCl_2 may be that more Cl^- will compete with TSA^- to dope into the PPy main chain with increasing amounts of FeCl_2 and lead to higher doping levels, which was confirmed by XPS data. As shown in Figure 2c, the binding energies of N 1s at 399.71 and 401.02 eV are observed, which are assigned to the undoped ($-\text{NH}-$) and doped ($-\text{N}^+-$) state of PPy, respectively.¹² The peak at 401.02 eV indicates that the PPy/ $\gamma\text{-Fe}_2\text{O}_3$ composite nanospheres contain PPy in its doped state. The doping level can be calculated from the $[-\text{N}^+-]/[-\text{NH}-]$ ratio. The doping

Figure 2. X-ray photoelectron spectra for PPy/ γ -Fe₂O₃ composite nanospheres prepared at the [Fe^{II}]/[Fe^{III}] ratio of 0.046: (a) full survey spectrum; (b) expanded spectra of Fe 2p; (c) expanded spectra of N 1s.

Figure 3. Dependence of magnetization on the applied magnetic field at room temperature for PPy/ γ -Fe₂O₃ composite nanospheres synthesized at different [Fe^{II}]/[Fe^{III}] ratios: (a) 0.014, (b) 0.035, (c) 0.046, and (d) 0.058.

level of PPy/ γ -Fe₂O₃ composite nanospheres increases from 28.07% to 37.24% when the [Fe^{II}]/[Fe^{III}] ratio increases from 0.014 to 0.046, which is consistent with the increase of conductivity.

In fact, the conductivity of PPy/ γ -Fe₂O₃ composite nanospheres depends on two main factors: PPy and magnetic γ -Fe₂O₃ in the composite. Increasing the amount of FeCl₂ enhances the conductivity of PPy because the doping level increased from 28.07% to 37.24% when the [Fe^{II}]/[Fe^{III}] ratio increased from 0.014 to 0.046. At the same time, there is more magnetic γ -Fe₂O₃ produced with an increase in the amount of FeCl₂, which will result in a decrease in the conductivity of the PPy/ γ -Fe₂O₃ composite. There are thus two competitive processes that contribute to the conductivity of the PPy/ γ -Fe₂O₃ composite with increasing FeCl₂ amounts. In the earlier article,⁸ the conductivity of the polyaniline/ γ -Fe₂O₃ nanofibers decreased with increasing amounts of FeCl₂ because the decrease produced by γ -Fe₂O₃ exceeds the increase resulting from polyaniline. In our present ICOSM, it is obvious that the increase resulting from PPy exceeds the decrease produced by γ -Fe₂O₃.

Figure 4. SEM images of PPy/ γ -Fe₂O₃ composites prepared at different [TSA]/[Py] molar ratios: (a) 0, (b) 1, (c) 2, and (d) 3.

The increase in the electrical and magnetic properties with increasing amount of FeCl₂ is also different from the result reported by Zhang,¹³ in which the increased amount of FeCl₂ resulted in higher magnetic properties but had no obvious effect on the conductivity of the PPy/Fe₃O₄ composite nanotubes. In Zhang's one-step method, pyrrole monomer, *p*-TSA, and FeCl₃ reacted for 2 h at first, and then FeCl₂ and ammonia were added to the solution. This method was indeed a two-step method because it contained two completely separate reaction processes. The polymerization of pyrrole was finished in the first 2 h, and magnetic Fe₃O₄ was formed when the FeCl₂ and ammonia were added after the formation of PPy. So the addition of FeCl₂ has little influence on the conductivity of PPy/Fe₃O₄ composite nanotubes.

Figure 5. SEM images and EDAX spectra of PPy/ γ -Fe₂O₃ composites prepared at different $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratios: (a, b) 0.014, (c, d) 0.023, (e, f) 0.046, and (g, h) 0.058.

Figure 3 shows that the PPy/ γ -Fe₂O₃ composite nanospheres exhibit superparamagnetic behavior (i.e., no hysteric loop), and the saturation magnetization of the PPy/ γ -Fe₂O₃ composite nanospheres increases from 0.96 to 4.85 A m²/kg with an increase in the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio from 0.014 to 0.046. This is because there are more γ -Fe₂O₃ magnetic particles formed when the amount of FeCl₂ is increased, which is similar to the results reported in the previous COSM.^{8,9} However, the saturation magnetization decreases when the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio is greater than 0.046.

3.2. Morphology. The uniform PPy/ γ -Fe₂O₃ composite nanospheres were prepared successfully by using this ICOSM. In order to optimize the formation conditions for the PPy/ γ -Fe₂O₃ composite nanospheres, the molar ratio of *p*-TSA to Py and the $[\text{Fe}^{\text{II}}]/[\text{Fe}^{\text{III}}]$ ratio in the reaction solution were investigated. It was found that $[\text{TSA}]/[\text{Py}]$ molar ratio plays an important role in the formation of PPy/ γ -Fe₂O₃ nanospheres. When $[\text{TSA}]/[\text{Py}]$ molar ratio is 2, the uniform PPy/ γ -Fe₂O₃ composite nanospheres were successfully prepared by ICOSM

Figure 6. X-ray diffraction patterns of PPy, PPy/ γ -Fe₂O₃ nanospheres, and γ -Fe₂O₃: (a) PPy doped with *p*-TSA; (b) PPy/ γ -Fe₂O₃ nanospheres prepared with [Fe^{II}]/[Fe^{III}] ratio of 0.046; (c) PPy/ γ -Fe₂O₃ nanospheres prepared with [Fe^{II}]/[Fe^{III}] ratio of 0.023; (d) standard γ -Fe₂O₃ (JCPDS No. 25-1402).

(Figure 4c). However, no uniform nanospheres can be observed (Figures 4b,d) when the [TSA]/[Py] molar ratio is lower than 1 or higher than 3. It needs to be noted that PPy/ γ -Fe₂O₃ massive aggregates were obtained without any dopant added (Figure 4a). This result shows that *p*-TSA played a vital role in controlling the nanospheric morphology. Figure 5 shows the SEM images and EDAX spectra of the PPy/ γ -Fe₂O₃ composites synthesized by using ICOSM at different FeCl₂ amounts when the [TSA]/[Py] molar ratio was kept at 2. It can be seen that the FeCl₂ amounts had no obvious effect on the spherical morphology, and uniform PPy/ γ -Fe₂O₃ composite nanospheres can be obtained for all selected [Fe^{II}]/[Fe^{III}] ratios (e.g., 0.014, 0.023, 0.046, and 0.058). Moreover, FeCl₂ amounts also had little influence on the diameter of the resulting PPy/ γ -Fe₂O₃ nanospheres. The diameters of all PPy/ γ -Fe₂O₃ nanospheres are \sim 80 nm. The EDAX spectra (Figures 5b,d,f, h) of PPy/ γ -Fe₂O₃ composites show that C, N, Cl, S, and Fe, O elements were included in the nanospheres, which identified that the nanospheres are composed of PPy and iron oxide.

3.3. Formation Mechanism of PPy/ γ -Fe₂O₃ Nanospheres.

As reported in the Experimental Part, the aqueous FeCl₂ solution was added into the white emulsion of pyrrole and ammonia aqueous solution. Pyrrole micelles containing Fe²⁺ ions might be formed. According to previous reports,¹⁴ the above-described micelles are regarded as the “soft templates” to form the electromagnetic composite nanospheres via a self-assembly process. The growth of the PPy nanostructures is allowed by an accretion¹⁵ or elongation process.¹⁶ It is obvious that the accretion process dominated in this ICOSM. In this process, FeCl₃ acts both as the oxidant for the polymerization of pyrrole to PPy and as a source of Fe^{III} for the formation of magnetic γ -Fe₂O₃. It is essential to add FeCl₂ and ammonia at the beginning for the formation of γ -Fe₂O₃.¹⁰ The beginning pH value of the reaction solution is about 11–12 produced by ammonia, which is necessary and beneficial for the formation of Fe₃O₄ and then γ -Fe₂O₃. When the FeCl₃ was added, Fe³⁺ reacts with Fe²⁺ from the preadded FeCl₂ to form magnetic γ -Fe₂O₃ first in the base solution (pH = 11–12). With the addition of FeCl₃, pyrrole is also oxidized to PPy and Fe²⁺ is produced. Although Fe²⁺ can be

produced with the oxidation polymerization of pyrrole, the Fe²⁺ produced is not available as a Fe²⁺ source to form Fe₃O₄ and then γ -Fe₂O₃. This is because the pH value of the reaction solution decreased promptly to <7 with the addition of FeCl₃, and the low pH value of the solution does not meet the strongly basic condition required for the formation of Fe₃O₄. Moreover, the extra *p*-TSA dopant was added in the reaction after the addition of the FeCl₃ aqueous solution. It was expected that the *p*-TSA would take part in the doping of PPy to improve the conductivity of PPy composites, and the presence of *p*-TSA in the product was shown by the XPS data. More Cl[−] will compete with TSA[−] to dope into the PPy main chain with increasing FeCl₂ content and lead to a higher doping level, which was also confirmed by the XPS data (Figure 2a).

3.4. Structural Characterization. Figure 6 shows the XRD patterns of PPy, PPy/ γ -Fe₂O₃ nanospheres, and standard γ -Fe₂O₃. Only a broad peak centered at $2\theta = 25.1^\circ$ is observed in the XRD pattern of PPy doped with *p*-TSA as shown in Figure 6a. Figures 6b,c show the XRD patterns of PPy/ γ -Fe₂O₃ nanospheres obtained at the different FeCl₂ amounts. Apart from a broad peak attributed to PPy, the sharp peaks at $2\theta = 30.4^\circ$, 35.7° , 43.4° , 53.8° , 57.3° , and 62.9° are observed in the PPy/ γ -Fe₂O₃ composite nanospheres, which correspond to the standard peaks of γ -Fe₂O₃ (JCPDS file No. 25-1402, Figure 6d).¹⁷ This result indicates that γ -Fe₂O₃ exists in the PPy/ γ -Fe₂O₃ composite nanospheres. The existence of γ -Fe₂O₃ was further supported by the XPS spectra, which is a powerful tool to differentiate between Fe₂O₃ and Fe₃O₄. As shown in Figure 2b, the photoelectron peaks at 711.1 and 724.4 eV, which are the characteristic doublets of Fe 2p_{3/2} and 2p_{1/2} core-level spectra of iron oxide, respectively, were observed for PPy/ γ -Fe₂O₃ composite nanospheres. A relatively weak Fe 3p line at 55.9 eV was also detected. Both Fe 2p and 3p data matched very well with those of γ -Fe₂O₃ reported in the literature.¹⁸ Moreover, these characteristic peaks of γ -Fe₂O₃ in the XRD pattern of PPy/ γ -Fe₂O₃ nanospheres prepared with a [Fe^{II}]/[Fe^{III}] ratio of 0.046 are stronger than those of γ -Fe₂O₃ in the XRD pattern of PPy/ γ -Fe₂O₃ nanospheres at a [Fe^{II}]/[Fe^{III}] ratio of 0.023, which shows that more magnetic γ -Fe₂O₃ formed in the

Figure 7. FTIR spectra for PPY/ γ -Fe₂O₃ composite nanospheres prepared at different [Fe^{II}]/[Fe^{III}] ratios: (a) 0.014 and (b) 0.046.

PPY/ γ -Fe₂O₃ composite nanospheres when the [Fe^{II}]/[Fe^{III}] ratio is 0.046. This result corresponds to the trend observed in their magnetic properties. Besides, all elements including C, N, S, Cl and Fe, O were found in the XPS spectra of the prepared composite nanospheres (Figure 2a), which further confirmed that the prepared nanospheres are composed of polypyrrole and γ -Fe₂O₃. Moreover, the presence of S and Cl in the XPS spectra indicated that both TSA[−] and Cl[−] are doped into the PPY main chain.

Figure 7 shows the FTIR spectra of PPY/ γ -Fe₂O₃ nanospheres obtained using different amounts of FeCl₂. The characteristic absorption bands at 1550, 1453, 1313, 1186, 1037, and 885 cm^{−1} for the PPY/ γ -Fe₂O₃ composite nanospheres are similar to those of PPY/FeOOH and PPY/Fe₃O₄ synthesized via the previous COSM.^{9,13} The peaks at 1550 and 1453 cm^{−1} are ascribed to the C=C and C–N stretching vibrations. The peaks at 1313 and 1186 cm^{−1} correspond to the C–H in-plane vibration. The peaks at 1037 and 885 cm^{−1} are attributed to the C–H in-plane bending and the ring deformation, respectively. These results indicate that the structure of the main PPY chain in the PPY/ γ -Fe₂O₃ nanospheres prepared by the ICOSM is identical to those of the PPY/FeOOH and PPY/Fe₃O₄ nanostructures prepared by the previous COSM.^{9,13}

4. CONCLUSION

PPY/ γ -Fe₂O₃ composite nanospheres with high conductivity (42.9–64.4 S/cm), good saturation magnetization (\sim 4.85 A m²/kg), and superparamagnetic properties (H_c = 0) were successfully prepared by an improved chemical one-step method (ICOSM). In this ICOSM, FeCl₃ acted both as the oxidant for the polymerization of pyrrole and as a source of Fe^{III} for the formation of γ -Fe₂O₃ magnets. Also, *p*-TSA as the dopant was added after the addition of FeCl₃, which played a very important role in enhancing the electrical properties and controlling the spherical morphology. Importantly, synchronous increasing and reaching the optimal electrical and magnetic properties of PPY/ γ -Fe₂O₃ composite nanospheres can be realized by controlling the amounts of dopant and FeCl₂. Both the best saturation magnetization (4.85 A m²/kg) and highest conductivity (64.4 S/cm) can be achieved for PPY/ γ -Fe₂O₃ nanospheres in the same

material when the [Fe^{II}]/[Fe^{III}] ratio is 0.046. This ICOSM is thus a very simple and significant method for the preparation of highly conductive PPY/ γ -Fe₂O₃ nanospheres with good magnetic properties, which opens a new way for the industrial application of electromagnetic conducting polymer nanostructures and will be a very useful to guide for the preparation of multifunctional nanostructured materials in a large quantity.
